The earliest recorded approaches to assess and treat mental distress were a mixture of non-secular, magical, and/or medical perspectives. Within the early 19th century, one approach to review mental conditions and behavior was using phrenology, the study of personality by examining the form of the skull. Other popular treatments at that point included the study of the form of the face (physiognomy) and Mesmer's treatment for mental conditions using magnets (mesmerism). Spiritualism and Phineas Quimby's "mental healing" were also popular.

While the scientific community eventually came to reject all of those methods for treating psychological state, academic psychologists also weren't concerned with serious kinds of mental state. The study of mental disease was already being drained the developing fields of psychiatry and neurology within the asylum movement. It had been not until the top of the 19th century, round the time when Sigmund Freud was first developing his "talking cure" in Vienna that the primary scientific application of mental hygiene began. WWII helped bring dramatic changes to mental hygiene, not just in America but internationally furthermore. Graduate education in psychology began adding psychotherapy to the science and research focus supported the 1947 scientist-practitioner model, known today because the Boulder Model, for Ph.D. programs in mental hygiene. Mental hygiene in Britain developed very like within the U.S. after WWII, specifically within

the context of the National Health Service with qualifications, standards, and salaries managed by country Psychological Society. In clinical practice, clinical psychologists may go with individuals, couples, families, or groups in a very sort of settings, including private practices, hospitals, psychological state organizations, schools, businesses, and non-profit agencies. Clinical psychologists who provide clinical services can also prefer to specialize. Some specializations are codified and credentialed by regulatory agencies within the country of practice.

Clinical psychologists add a spread of settings, including hospitals, clinics, and corporations, and privately practice. Some focus on working with mentally or physically handicapped persons, prison inmates, drug and alcohol abusers, or geriatric patients. In some settings, a psychotherapist works in tandem with a psychiatrist and a caseworker and is accountable for conducting the team's research. Clinical psychologists also serve the courts in assessing defendants or potential parolees, et al are employed by the militia to gauge or treat service personnel. Clinical psychologists are trained to assemble data by observing behavior. The clinical interview may be a vital part of the assessment, even when using other formalized tools, which may employ either a structured or unstructured format. Such assessment looks at certain areas, like general appearance and behavior, mood and affects, perception, comprehension, orientation, insight, memory, and content of the communication. One psychiatric example of a proper interview is that the mental status examination, which is usually employed in psychiatry as a screening tool for treatment or further testing.
